

Blocked Plumbing Vent Problems

Craig Kessler

Plumbing vents are in fact vertical pipes which go from water and sewer pipes, through the walls, then right up and out of the roofing of the house. Such vents let air into the piping which will hold pressure in balance which allows everything to move along the pipes efficiently and rapidly. These vents may without difficulty get plugged, though, which may lead to plumbing clogs. Plumbing clogs might manifest in several different ways which include bad smells, slow-moving drains, and backups. Drain and sewer line blockages occur commonly and for many reasons, but there are a few indications to look for whenever you are concerned a plumbing vent could be blocked.

What Leads to Plumbing Vents Blockages

There are actually numerous ways plumbing vents might get clogged or **blocked**. Given that they are simply open pipes sticking out of the roof, it is somewhat simple for them to get blocked or stopped up. Here are a few of the primary ways plumbing vents get blocked up:

Animals

Bird nests
Foliage
Corrosion

Many of these are without difficulty taken care of, though some problems, like rust, are more challenging. Plumbing vents are the same as every other pipe and, as time passes, probably will have to be replaced because of rust. It is advisable to be familiar with exactly how old your pipes are so you recognize when that time could be approaching.

Indications of a Cedar Hill Plumbing Vent Blockage

There are three principal indicators that a plumbing blockage is being brought on by a vent blockage; toilets gurgling whenever flushed, slow-moving drains, and sewer odors. Although these types of problems may, obviously, be resulting from other elements, a plumbing vent clog may be a simple mend for many. As stated earlier, frequently with vent blockages, repairs aren't as devastating as having to replace a pipe or total vent system. In cases where a gurgling commode is the issue, it is probably a good sign. In nearly all scenarios, gurgling toilets do not gradually get worse, it simply starts gurgling some day before it gets repaired. The gurgling is commonly caused by an obstruction in the entry of the pipe such as a bird's home or leaves. This issue occurs since not enough air is getting into the water system via the plumbing vent causing there to be excessive pressure. Whenever you go to flush the toilet the water is struggling with the pressure when it's attempting to move down the drain.

[Slower drains](#) may be brought on by a number of plumbing problems, but the plumbing vent being blocked can cause this too. For the exact same reason as the commode making a gurgling sound when it is getting forced down a drain having high pressure, other drains will drain more slowly. Other drains in the home are not being forced down, which means that they aren't being forced to battle the high pressure in the plumbing, the water simply runs down the drain at a sluggish rate, when a blockage within the vent is the culprit. An undesirable smell of [sewer gas](#) can be another issue that could be due to a blocked vent or it may be a result of something different.

The best thing to do if you are encountering any of these 3 issues would be to have a specialist take a look at the vent entry on the rooftop. If perhaps the pipe looks okay, in that case, at least, the vent will be eliminated. The best preventative maintenance for plumbing vents is to monitor the roofing to make sure there are no over hanging branches and keep track of how old the plumbing is in your house.
